The background situation

The customer was looking for a new entrant into the supplier loop, to challenge the incumbent supplier group.

Other competitors were reaching a typical lifetime of 30 heats (4676 contact minutes - 155 minutes on average) with a remaining residual thickness of 60mm.

The request from the customers

- Bringing new product with tailor made solutions, in order to improve average performance.

The customer has the following process parameters:

- 500k tonne p.a.
- EHF>LF>VOD(100%)>CC
- Carbon / Alloy / Stainless Steel product Mix

| | | |
|---------------------------|-------|---------------------|
| Ladle capacity | Ton | 100 |
| Total Ladles in plant | No | 14 |
| Total Ladles in Operation | No | 6 |
| Av Heats / day | No | 18 (14 - 22) |
| Preheating Time | Hours | 16 |
| Preheating T° | °C | 1100 |
| Maximum Tapping T° | °C | 1760 (Alloy Steels) |

| | | |
|---------------------------------------|-----|------------------------|
| Average heats / campaign | No | 60 |
| Slag Zone replacement | | Yes at 30 heats |
| Lining weak point | | Slag Line purging zone |
| Number of Relines per year | No | >100 |
| Specific Consumption of Ladle Gunning | Yes | 200 t per year |
| Number of porous plugs | No | 1 |
| Average Steel residence time/heat | Min | 180 |
| Max Steel residence time/heat | Min | 400 (Alloy Steels) |
| Fluorspar addition using | | NO |

Calderys offer

The Calderys proposal was to provide a dual zone slag line: one for the purging zone area (66%), and one for the none purging zone.

Whilst the customer only used one purge plug at one time, there was two possible purging locations depending on purging plug life/availability.

Calderys Solution

Calderys offered two products from its deep product portfolio.

The ladle slag line (None purging) is made of **CALDE BRICK MC R 7026**, magnesia resin bonded carbon brick based on fused magnesite with high refractoriness and slag resistance.

The ladle slag line is made of **CALDE BRICK MC R 8026** magnesia resin bonded carbon brick based on fused magnesite LC with high refractoriness and slag resistance, manufactured in our plant in Turkey.

Benefits brought by the solution

The ladle slag line performance for the original lining was **30 heats, with over 4000 contact minutes**. Residual thickness were well in excess of the required minimum of 60mm, with the lowest measurable point being 115 mm within the slag line.

The free board area did show some thinner sections, being as low as 70mm in places, but the customer would typically progress some lip ring / freeboard gunning in normal circumstances, but this was required for the Calderys trial.

30 heats

Product selection validated, next steps

The slagline product selection combination of 7026 and 8026 has proven successful, and has changed the dynamic in terms of the potential lifetime of the ladle. Indeed, with such a significant increase in lifetime, other factors will need to be closely considered to ensure that any new lifetime is fully realised, the performance of the purging block, wellblock and other elements of the lining will need to be reviewed to ensure these elements do not become the new bottleneck.
